'TWISTED DUALITY' IN THE C* CLIFFORD ALGEBRA

P.L. ROBINSON

Abstract. Let V be a real inner product space and $C[V]$ its C* Clifford algebra. We prove that if Z is a subspace of V then $C[Z^\perp]$ coincides with the supercommutant of $C[Z]$ in $C[V]$.

0. Introduction

Let V be a real vector space on which $(\cdot|\cdot)$ is an inner product. Denote by $C(V)$ the associated complex Clifford algebra: thus, $C(V)$ is a unital associative complex algebra containing and generated by its real subspace V subject to the Clifford relations

$$(\forall v \in V)\ v^2 = (v|v)\mathbf{1}$$

and it admits a unique involution * for which each element of V is selfadjoint. This involutive algebra carries a natural norm $||\cdot||$ that satisfies the C* property; the C*-algebra obtained upon its completion is the C* Clifford algebra $C[V]$.

For our purposes, it is important to note that these Clifford algebras are naturally $\mathbb{Z}_2$-graded: they are *superalgebras*. Explicitly, the complex algebra $C(V)$ carries a unique automorphism γ that restricts to $V \subseteq C(V)$ as $-\mathrm{Id}$; accordingly, $C(V)$ has an eigendecomposition

$$C(V) = C(V)_+ \oplus C(V)_-$$

in which

$$C(V)_+ = \ker(\gamma - \mathrm{Id})$$

is the even Clifford algebra and

$$C(V)_- = \ker(\gamma + \mathrm{Id})$$

is the odd subspace. The grading automorphism γ extends continuously to the C* Clifford algebra $C[V]$ and thereby yields a corresponding eigendecomposition

$$C[V] = C[V]_+ \oplus C[V]_-.$$

We remark that the closure of V in $C[V]$ is a copy of its Hilbert space completion, for which also $C[V]$ serves as the C* Clifford algebra; accordingly, we may and shall assume that V is a real Hilbert space. Likewise, we may and shall take subspaces of V that appear below to be closed.

Thus, let Z be a (closed) subspace of V and $Z^\perp$ its orthocomplement, so that

$$V = Z \oplus Z^\perp$$

is an orthogonal direct sum decomposition of the real Hilbert space V. Regarding $C[V]$ as a superalgebra, the *supercommutant* $C[Z]'$ of $C[Z]$ within $C[V]$ is

$$C[Z]' = C[Z]'_+ \oplus C[Z]'_-$$

with even part

$$C[Z]'_+ = \{a \in C[V]_+ | (\forall b \in C[Z])\ ba = ab\}$$

and odd part

$$C[Z]'_- = \{a \in C[V]_- | (\forall b \in C[Z])\ ba = a\gamma(b)\}.$$

Thus: *even* elements of $C[Z]'$ commute with each element of $C[Z]$; *odd* elements of $C[Z]'$ commute with even elements of $C[Z]$ and anticommute with odd elements of $C[Z]$. As elements of V itself are odd, it follows that

$$C[Z]' = \{a \in C[V] | (\forall z \in Z)\ za = \gamma(a)z\}.$$

Our purpose in this note is to prove the following version of 'twisted duality'.

Theorem 1. $C[Z]' = C[Z^\perp]$.

For the origins and development of 'twisted duality' see [2] [6] [3] [1]; several proofs of 'twisted duality' for the plain complex Clifford algebra in line with the present account are presented in [5]; and [4] is a convenient reference for the theory of Clifford algebras.

1. Conditional expectations and twisted duality

Our approach to twisted duality will be via conditional expectations: we shall construct a conditional expectation

$$\mathbb{E}_Z : C[V] \to C[Z^\perp]$$

that fixes the subalgebra $C[Z]'$ pointwise; this establishes the inclusion $C[Z]' \subseteq C[Z^\perp]$ while the reverse inclusion $C[Z^\perp] \subseteq C[Z]'$ is immediate from the (linearized) Clifford relations.

We shall find it convenient to denote by $\mathcal{F}(V)$ the set of all finite-dimensional subspaces of V directed by inclusion and to observe that

$$C(V) = \bigcup_{M \in \mathcal{F}(V)} C(M).$$

To begin, let $u \in V$ be a unit vector and $u^\perp \subseteq V$ its orthogonal space. The Clifford algebra of V decomposes naturally as

$$C(V) = C(u^\perp) \oplus u\, C(u^\perp).$$

To see this, let $c \in C(V)$ and choose $M \in \mathcal{F}(V)$ containing u so that $c \in C(M)$; augment u to an orthonormal basis for M and expand c relative to this basis. Suppose that in this decomposition,

$$c = a + ub$$

with $a, b \in C(u^\perp)$. Then $\gamma(a)u = ua$ and $\gamma(b)u = ub$ on account of the (linearized) Clifford relations, so that

$$u\gamma(c)u = u\gamma(a)u + u\gamma(ub)u = a - ub$$

because the unit vector u has square $\mathbf{1}$ and is odd. It follows that the projector

$$E_u : C(V) \to C(u^\perp) \subseteq C(V)$$

of $C(V)$ on $C(u^\perp)$ along $uC(u^\perp)$ is given by

$$(\forall c \in C(V))\ E_u(c) = \frac{1}{2}(c + u\gamma(c)u).$$

Let $M \in \mathcal{F}(V)$ be a finite-dimensional subspace of V. If $\{u_1, \ldots, u_m\}$ is an orthonormal basis for M then the projectors $E_{u_1}, \ldots, E_{u_m}$ commute, as is shown by direct calculation using the Clifford relations; the product

$$E_M = E_{u_1} \circ \cdots \circ E_{u_m}$$

projects $C(V)$ on $C(u_{u_1}^\perp) \cap \cdots \cap C(u_{u_m}^\perp) = C(M^\perp)$.

Let Z be an arbitrary (closed) subspace of V. Let $c \in C(V)$ and choose $M \in \mathcal{F}(V)$ so that $c \in C(M)$. Let $X \in \mathcal{F}(Z)$ be the orthogonal projection of M on Z and $Y \in \mathcal{F}(Z^\perp)$ its orthogonal projection on $Z^\perp$; thus $M \subseteq X \oplus Y$. Apply E_X to $c \in C(X \oplus Y)$ to obtain

$$E_X(c) \in C((X \oplus Y) \cap X^\perp) = C(Y) \subseteq C(Z^\perp);$$

if $u \in Z$ is any unit vector then $uE_X(c)u = E_X(c)$ by the Clifford relations, so

$$E_u \circ E_X(c) = E_X(c).$$

Now, if $N \in \mathcal{F}(Z)$ is any finite-dimensional subspace of Z containing X then taking the product as u runs over an orthonormal basis for $N \cap X^\perp$ reveals that

$$E_N(c) = E_X(c).$$

This proves that the net $(E_N(c) | N \in \mathcal{F}(Z))$ is eventually constant and hence converges.

Thus, we construct a linear map

$$E_Z : C(V) \to C(Z^\perp) \subseteq C(V)$$

by the rule

$$(\forall c \in C(V))\ E_Z(c) = \lim_{N \uparrow \mathcal{F}(Z)} E_N(c).$$

Theorem 2. *If Z is a (closed) subspace of V then E_Z is contractive:*

$$(\forall c \in C(V))\ \|E_Z(c)\| \leqslant \|c\|$$

and has the (conditional expectation) property:

$$(\forall c \in C(V))(\forall \ell, r \in C(Z)')\ E_Z(\ell c r) = \ell\, E_Z(c)\, r.$$

Proof. The norm here is the natural one, completion of $C(V)$ relative to which yields $C[V]$. If $u \in V$ is a unit vector then $\|v\| = 1$ so that if $c \in C(V)$ then $\|E_u(c)\| \leqslant \|c\|$ because γ is isometric. Taking the product over an orthonormal basis shows that E_N is contractive when $N \in \mathcal{F}(V)$. That E_Z itself is contractive follows immediately. If $u \in Z$ is a unit vector then $u\gamma(\ell) = \ell u$ and $\gamma(r)u = ur$ so that $u\gamma(\ell c r)u = \ell u \gamma(c) u r$ and therefore $E_u(\ell c r) = \ell E_u(c) r$. Taking the product over an orthonormal basis proves the conditional expectation property for E_N when N is a finite-dimensional subspace of Z. The conditional expectation property for E_Z itself follows upon taking $M \in \mathcal{F}(V)$ so large that c, ℓ, r lie in $C(M)$ and taking $N \in \mathcal{F}(Z)$ to contain the orthogonal projection of M on Z. □

We remark that the purely algebraic conditional expectation $E_Z : C(V) \to C(Z^\perp)$ fixes the supercommutant $C(Z)' \subset C(V)$ pointwise: if $a \in C(Z)'$ then $E_Z(a) = a$ as follows at once from Theorem 2 by taking (say) $\ell = a$ and $c = r = \mathbf{1}$. In particular, this implies that $C(Z)' \subseteq C(Z^\perp)$; the Clifford relations yield the reverse $C(Z^\perp) \subseteq C(Z)'$. In this way, we establish Theorem 1 for the plain complex Clifford algebra C(V).

As the linear map $E_Z : C(V) \to C(Z^\perp) \subseteq C(V) \subseteq C[V]$ is a contraction, it extends continuously to a contraction

$$\mathbb{E}_Z : C[V] \to C[Z^\perp].$$

Note that if $N \in \mathcal{F}(V)$ has orthonormal basis $\{u_1, \ldots, u_n\}$ then the obvious factorization

$$\mathbb{E}_N = \mathbb{E}_{u_1} \circ \cdots \circ \mathbb{E}_{u_n}$$

holds by continuous extension of its counterpart on the plain complex Clifford algebra, where if $u \in V$ is a unit vector then

$$\mathbb{E}_u : C[V] \to C[V] : c \mapsto \frac{1}{2}(c + u\gamma(c)u).$$

Theorem 3. *If Z is a (closed) subspace of V and $c \in C[V]$ then the net*

$$(\mathbb{E}_N(c) | N \in \mathcal{F}(Z))$$

converges to $\mathbb{E}_Z(c)$:

$$\mathbb{E}_Z(c) = \lim_{N \uparrow \mathcal{F}(Z)} \mathbb{E}_N(c).$$

Proof. Let $\varepsilon > 0$. Choose $c_\varepsilon \in C(V)$ so that $\|c - c_\varepsilon\| \leqslant \varepsilon$. Choose $M_\varepsilon \in \mathcal{F}(V)$ so that $c_\varepsilon \in C(M_\varepsilon)$ and let $X_\varepsilon \in \mathcal{F}(Z)$ be the orthogonal projection of M_ε on Z. Now, let $N \in \mathcal{F}(Z)$ contain X_ε: as $\mathbb{E}_Z$ and $\mathbb{E}_N$ are contractions, $\|\mathbb{E}_Z(c) - \mathbb{E}_Z(c_\varepsilon)\| \leqslant \varepsilon$ and $\|\mathbb{E}_N(c_\varepsilon) - \mathbb{E}_N(c)\| \leqslant \varepsilon$; also, $\mathbb{E}_Z(c_\varepsilon) = E_Z(c_\varepsilon) = E_N(c_\varepsilon) = \mathbb{E}_N(c_\varepsilon)$. According to the triangle inequality, it follows that if $\mathcal{F}(Z) \ni N \supseteq X_\varepsilon$ then $\|\mathbb{E}_Z(c) - \mathbb{E}_N(c)\| \leqslant 2\varepsilon$ and the proof is complete. □

We are now able to establish Theorem 1 in full.

Proof of Theorem 1. As noted previously, the Clifford relations yield $C[Z^\perp] \subseteq C[Z]'$. We need only prove the reverse inclusion, so let $c \in C[Z]'$. Recall the formulae displayed prior to Theorem 3: if $u \in Z$ is a unit vector, then $\mathbb{E}_u(c) = c$; taking the product as u runs over an orthonormal basis, it follows that if $N \in \mathcal{F}(Z)$ then $\mathbb{E}_N(c) = c$. Finally, Theorem 3 allows us to pass to the limit as N runs over $\mathcal{F}(Z)$ to conclude that $c = \mathbb{E}_Z(c) \in C[Z^\perp]$.

□

We announced that $\mathbb{E}_Z : C[V] \to C[Z^\perp]$ would be a conditional expectation; indeed it is. Let $c \in C[V]$ and let $\ell, r \in C[Z^\perp] = C[Z]'$; choose sequences $C(V) \ni c_n \to c$, $C(Z^\perp) \ni \ell_n \to \ell$ and $C(Z^\perp) \ni r_n \to r$. The conditional expectation property of E_Z in Theorem 2 justifies the middle step in

$$\mathbb{E}_Z(\ell_n c_n r_n) = E_Z(\ell_n c_n r_n) = \ell_n E_Z(c_n) r_n = \ell_n \mathbb{E}_Z(c_n) r_n$$

whence continuity of $\mathbb{E}_Z$ and passage to the $n \to \infty$ limit yield the required identity

$$\mathbb{E}_Z(\ell c r) = \ell\, \mathbb{E}_Z(c)\, r.$$

Further, $\mathbb{E}_Z$ preserves the involution * and in fact preserves positivity. Let $c \in C(V)$: if $u \in V$ is a unit vector then

$$E_u(c^*c) = \frac{1}{2}(c^*c + (\gamma(c)u)^*(\gamma(c)u))$$

is a convex combination of terms d^*d for $d \in C(V)$ so the same is true of $E_N(c^*c)$ whenever $N \in \mathcal{F}(Z)$ and therefore true of $E_Z(c^*c)$; by continuity, it follows that $\mathbb{E}_Z(c^*c) \geqslant 0$ whenever $c \in C[V]$. Of course, $\mathbb{E}_Z$ is idempotent.

We close by offering what is perhaps an eccentric application of 'twisted duality'.

Theorem 4. *If $\{Z_\lambda | \lambda \in \Lambda\}$ is any family of (closed) subspaces of V then*

$$\bigcap_{\lambda \in \Lambda} C[Z_\lambda] = C[\bigcap_{\lambda \in \Lambda} Z_\lambda].$$

Proof. Only $\subseteq$ is in question, so let $c \in \bigcap_{\lambda \in \Lambda} C[Z_\lambda]$. If $\lambda \in \Lambda$ then $c \in C[Z_\lambda] \subseteq C[Z_\lambda^\perp]'$ by (easier direction) 'twisted duality' so that if also $v \in Z_\lambda^\perp$ then $vc = \gamma(c)v$. By linearity, it follows that

$$v \in \sum_{\lambda \in \Lambda} Z_\lambda^\perp \;\Rightarrow\; vc = \gamma(c)v$$

whence continuity yields

$$v \in \overline{\sum_{\lambda \in \Lambda} Z_\lambda^\perp} \;\Rightarrow\; vc = \gamma(c)v.$$

Recalling the Hilbert space identity

$$\overline{\sum_{\lambda \in \Lambda} Z_\lambda^\perp} = (\bigcap_{\lambda \in \Lambda} Z_\lambda)^\perp$$

we conclude from (harder direction) 'twisted duality' that

$$c \in C[\overline{\sum_{\lambda\in\Lambda} Z_\lambda^\perp}]' \subseteq C[(\overline{\sum_{\lambda\in\Lambda} Z_\lambda^\perp})^\perp] = C[\bigcap_{\lambda\in\Lambda} Z_\lambda].$$
